Noisy Intermediate-Scale Quantum algorithms

A universal fault-tolerant quantum computer that can solve efficiently problems such as integer factorization and unstructured database search requires millions of qubits with low error rates and long coherence times. While the experimental advancement towards realizing such devices will potentially take decades of research, noisy intermediate-scale quantum (NISQ) computers already exist. These computers are composed of hundreds of noisy qubits, i.e. qubits that are not error-corrected, and therefore perform imperfect operations in a limited coherence time. In the search for quantum advantage with these devices, algorithms have been proposed for applications in various disciplines spanning physics, machine learning, quantum chemistry and combinatorial optimization. The goal of such algorithms is to leverage the limited available resources to perform classically challenging tasks. In this talk, I provide an overview of NISQ computational paradigms and algorithms, discussing the key structure of these algorithms, their limitations and their advantages.

Thursday 4th of MARCH 2021 AT 3.00 P.M.

Two short talks will follow:

4pm: Dr. Simon Apers (ULB)

« $qLx=b$, or quantum algorithms for Laplacian solving »

4:30pm: Renaud Chrétien (Univ. Liege)

« Inversion of coherent backscattering with interacting Bose-Einstein condensates in two-dimensional disorder : a Truncated Wigner approach »

This BQPi Meeting will be held online (ZOOM)
